

Panel A: rate at which prior matching reordered the three datasets by calibration, against null distributions that resample under the same protocol. Under a null of identical calibration across datasets (shaded band), prior matching alone reordered them in 82-84% of replicates; the observed rate exceeded this baseline in 7 of 8 model-label combinations ($p <= 2.9 \times 10^{-22}$). In the single exception (MIMIC-CXR with CheXpert labels, PNEUMONIA) the observed rate fell below the baseline. Panel B: calibration spread before and after matching; points below the dashed line indicate contraction. MIMIC-CXR (noise-handled) on PNEUMONIA shows the largest contraction.
