

Each point is the mean predicted probability and observed frequency within one of ten equal-width probability bins; the dashed diagonal denotes perfect calibration. Point size is proportional to the number of images in the bin, and bins holding fewer than 20 images are omitted. On NIH (left column), where only 2.3% of images are pneumonia-positive, the observed frequency stays near zero across the whole predicted range, indicating systematic overestimation. Kermany (centre column) attains the highest discrimination but its curve is compressed against the upper right of the diagonal, indicating poor calibration. Prior matching (dashed) moves the curves toward the diagonal and can change which dataset is best calibrated.
